(Received 5 September 2023; Revised 12 March 2024; Accepted 16 March 2024)

In this article, we present a new algorithmic implementation of exact three-point difference schemes for a certain class of singular Sturm–Liouville problems. We demonstrate that computing the coefficients of the exact scheme at any grid node \(x_j\) requires solving two auxiliary Cauchy problems for the second-order linear ordinary differential equations: one problem on the interval \([x_{j-1}, x_j]\) (forward) and one problem on the interval \([x_j, x_{j+1}]\) (backward). We have also proven the coefficient stability theorem for the exact three-point difference scheme.

Keywords: singular Sturm–Liouville problem; exact three-point difference scheme; coefficient stability.

2010 MSC: 65L15, 65L20

1. Introduction

Exact difference schemes for linear boundary value problems have been first introduced in [1,2]. These schemes allow for the construction of truncated difference schemes of any order of accuracy. In [3], these results were applied to the Sturm–Liouville problem, and in [4], to the singular Sturm–Liouville problem with coefficients of a special form.

However, the practical use of such truncated schemes in the case of variable coefficients of a differential equation requires the calculation of multiple integrals at each grid node \(x_j\), posing computational challenges. Addressing the need for high accuracy in practical calculations for nonlinear boundary value problems, truncated difference schemes of high order were developed in [5].

In [6, 7], building upon the ideas presented in [8, 9], a new algorithmic realization of the exact three-point difference scheme (ETDS) via truncated three-point difference schemes (TDS) of any order of accuracy was developed and justified for the Sturm–Liouville problem. These articles demonstrate that the coefficients of the ETDS and the right-hand side at any grid node can be expressed through the solutions of two auxiliary Cauchy problems, each of which can be numerically solved using any one-step method, such as the Taylor series expansion or the Runge–Kutta methods.

In this paper, we extend these findings by demonstrating that coefficients of the ETDS for the Sturm–Liouville problem with a singularity at the ends of the segment \([-1, 1]\) can also be expressed through solutions of the auxiliary Cauchy problems for second-order linear ordinary differential equations.

2. Exact three-point difference scheme for singular Sturm–Liouville problem

In the present article we consider the following singular Sturm–Liouville problem

\[
\frac{d}{dx} \left[ k(x) \frac{du}{dx} \right] - q(x)u(x) = -\lambda r(x)u(x), \quad x \in (-1, 1),
\]

\[
u(-1) \neq \infty, \quad u(1) \neq \infty,
\]
where 
\[ k(x) = (1 - x^2)k_1(x), \quad 0 < C_1 \leq k_1(x) \leq C_2, \quad 0 < C_3 \leq q(x) \leq C_4, \quad 0 < C_5 \leq r(x) \leq C_6, \quad (3) \]
\( C_i, i = 1, 2, \ldots, 6 \) are constants. We introduce the regular grid
\[ \omega_h = \{ x_j = -1 + (j - 0.5)h, \quad h = 2/N, \quad j = 1, 2, \ldots, N, \quad x_0 = -1, \quad x_{N+1} = 1 \} \]
and take the pattern functions \( v^j_i(x, \lambda), \quad \alpha = 1, 2, \quad j = 1, 2, \ldots, N \) as the solutions of the following Cauchy problems

\[ \frac{d}{dx} \left[ k(x) \frac{dv^1_i}{dx} \right] - q(x)v^1_i(x, \lambda) + \lambda r(x)v^1_i(x, \lambda) = 0, \quad x \in (x_0, x_2), \]

\[ v^1_i(x_0, \lambda) = 1, \quad k(x) \frac{dv^1_i}{dx} \bigg|_{x=x_0} = 0, \]

\[ \frac{d}{dx} \left[ k(x) \frac{dv^j_i}{dx} \right] - q(x)v^j_i(x, \lambda) + \lambda r(x)v^j_i(x, \lambda) = 0, \quad x \in (x_{j-1}, x_{j+1}), \]

\[ v^j_i(x_{j+(-1)}^0, \lambda) = 0, \quad k(x) \frac{dv^j_i}{dx} \bigg|_{x=x_{j+(-1)}^0} = (-1)^{\alpha + 1}, \]

\[ \alpha = 1, 2, \quad j = 3 - \alpha, 4 - \alpha, \ldots, N + 1 - \alpha, \]

\[ \frac{d}{dx} \left[ k(x) \frac{dv^N_i}{dx} \right] - q(x)v^N_i(x, \lambda) + \lambda r(x)v^N_i(x, \lambda) = 0, \quad x \in (x_{N-1}, x_{N+1}), \]

\[ v^N_i(x_{N+1}, \lambda) = 1, \quad k(x) \frac{dv^N_i}{dx} \bigg|_{x=x_{N+1}} = 0. \]

Similarly to [4], we establish the properties of the pattern functions.

**Lemma 1.** The functions \( v^j_i(x, \lambda) > 0, \quad \alpha = 1, 2 \) have the following properties:
1) \( v^j_i(x, \lambda) > 0, \quad \alpha = 1, 2 \) for all \( x \in (x_{j-1}, x_{j+1}) \) \( j = 1, 2, \ldots, N \) and are linearly independent at each of these intervals;
2) these functions satisfy the next relation

\[ v^j_i(x_{j+1}, \lambda) = v^j_i(x_{j-1}, \lambda), \quad j = 2, 3, \ldots, N - 1, \]

\[ v^j_i(x_2, \lambda) = v^j_i(x_1, \lambda) + v^j_i(x_1, \lambda) \int_{x_0}^{x_1} v^1_i(\xi, \lambda)[q(\xi) - \lambda r(\xi)] d\xi \]

\[ + v^1_i(x_1, \lambda) \int_{x_1}^{x_2} v^1_i(\xi, \lambda)[q(\xi) - \lambda r(\xi)] d\xi, \]

\[ v^j_i(x_{j+1}, \lambda) = v^j_i(x_j, \lambda) + v^j_i(x_j, \lambda) \int_{x_{j-1}}^{x_j} v^1_i(\xi, \lambda)[q(\xi) - \lambda r(\xi)] d\xi \]

\[ + v^1_i(x_j, \lambda) \int_{x_j}^{x_{j+1}} v^1_i(\xi, \lambda)[q(\xi) - \lambda r(\xi)] d\xi, \quad j = 2, \ldots, N - 1, \]

\[ v^N_i(x_{N-1}, \lambda) = v^N_i(x_N, \lambda) + v^N_i(x_N, \lambda) \int_{x_{N-1}}^{x_N} v^1_i(\xi, \lambda)[q(\xi) - \lambda r(\xi)] d\xi \]

\[ + v^1_i(x_N, \lambda) \int_{x_N}^{x_{N+1}} v^1_i(\xi, \lambda)[q(\xi) - \lambda r(\xi)] d\xi. \]

**Proof.**
1) We now prove that the functions \( v^j_i(x, \lambda), \quad \alpha = 1, 2, \) are linearly independent. As is known, for the linear independence of solutions of problem (4), (5) it is necessary and sufficient, that the Wronskian should be different from zero if at least in one point of the interval \([x_{j-1}, x_{j+1}]\). Let us assume the contrary for \( j = 2, 3, \ldots, N - 1 \). Then the Wronskian \( W[v^j_i(x, \lambda), v^j_i(x, \lambda)] \) is identically equal to zero on the interval \([x_{j-1}, x_{j+1}]\). Calculating the Wronskian at the points \( x_{j+(-1)}^0, \quad \alpha = 1, 2, \) and taking the fact that \( v^2(x_{j-1}, \lambda) = v^1_i(x_{j+1}, \lambda) \) into account, we obtain

It follows that $v_1^j(x_{j+1}, \lambda) = 0$, i.e., $v_1^j(x, \lambda)$ is the solution of boundary-value problem

$$
\frac{d}{dx} \left[ k(x) \frac{dv_1^j}{dx} \right] - q(x) v_1^j(x, \lambda) + \lambda r(x) v_1^j(x, \lambda) = 0, \quad x \in (x_{j-1}, x_{j+1}),
$$

$$
v_1^j(x_{j-1}, \lambda) = v_1^j(x_{j+1}, \lambda) = 0, \quad j = 2, 3, \ldots, N - 1.
$$

We now show that for sufficiently small $h < h_0$ and for $\lambda = \lambda_m$, $1 \leq m \leq k$, $k \ll N$, problem (7) has only the trivial solution. For this purpose, it is sufficient to show that for $h < h_0$ the following inequality is satisfied:

$$
-\{q(x) - \lambda r(x)\} \leq \lambda r(x) < \mu_1 \quad \forall x \in [x_{j-1}, x_{j+1}],
$$

where $\mu_1$ is the lower estimate of the smallest eigenvalue of the problem

$$
\frac{d}{dx} \left[ k(x) \frac{dv}{dx} \right] + \mu v(x) = 0, \quad x \in (x_{j-1}, x_{j+1}), \quad v(x_{j-1}) = v(x_{j+1}) = 0.
$$

This problem is known to be equivalent to the variational problem of finding the minimum of the functional

$$
\min \int_{x_{j-1}}^{x_{j+1}} k(\xi) [v'(\xi)]^2 \, d\xi
$$

under condition

$$
\|v\|^2 = \int_{x_{j-1}}^{x_{j+1}} v^2(x) \, dx = 1.
$$

Considering that $h < 1$, $x_{j-1} \leq \xi \leq x_{j+1}$ for $j = 2, 3, \ldots, N - 1$,

$$
k(\xi) > C_1(1 - \xi^2) > C_1[1 - (-1 + 0.5h)^2] = C_1 \left[ h - \frac{h^2}{4} \right] > \frac{3}{4} C_1
$$

and

$$
\min \int_{x_{j-1}}^{x_{j+1}} [v'(\xi)]^2 \, d\xi = \frac{\pi^2}{4h},
$$

we obtain $\mu_1 > \frac{3C_1 \pi^2}{16h} = \mu_1$. Hence, there exists $h_0$ such that for all $h < h_0$ the inequality

$$
h \lambda r(x) < \frac{3C_1 \pi^2}{16} \quad \forall x \in [x_{j-1}, x_{j+1}], \quad j = 2, 3, \ldots, N - 1
$$

is satisfied. Consequently, it follows that $v_1^j(x, \lambda) \equiv 0$, $x \in [x_{j-1}, x_{j+1}]$ for $h < h_0 = \frac{3C_1 \pi^2}{16AC_6}$, which contradicts the condition $k(x) \frac{dv_1^j(x, \lambda)}{dx} \bigg|_{x=x_{j-1}} = 1$.

Similar considerations show that $v_1^j(x, \lambda) \neq 0$ holds in any point of the interval $(x_{j-1}, x_{j+1}]$, i.e., our function is of constant-sign on this interval. Thus, $v_1^j(x, \lambda)$, $v_2^j(x, \lambda)$, $j = 2, 3, \ldots, N - 1$ are linearly independent on the interval $(x_{j-1}, x_{j+1}]$.

For $j = 1$ at $\lambda = \lambda_m$, $m = 1, 2, \ldots, k$, $k \ll N$, we have $v_1^j(x, \lambda) = c_m u_m(x)$, where $u_m(x)$ is the eigenfunction of the problem (1), (2) which corresponds to the eigenvalue $\lambda_m$. We denote by $x_{m\text{min}}^m$ the minimum, and by $x_{m\text{max}}^m$ the maximum zero of the function $u_m(x)$ on the interval $(-1, 1)$. If we choose $h < h_1 = \frac{2}{\pi}(1 + x_{m\text{min}}^m)$, then $x_2 = -1 + 1.5h < -1 + (1 + x_{m\text{min}}^m)$ = $x_{m\text{min}}^m$ is obtained. Hence, $v_1^1(x, \lambda) \neq 0$, $x \in [-1, x_2]$. From the fact that $v_1^1(x, \lambda) \neq 0$, follows the linear independence of the functions $v_1^j(x, \lambda)$, $v_2^j(x, \lambda)$. Similarly, for $j = N$ we get that for $h < h_2 = \frac{2}{\pi}(1 - x_{m\text{max}}^m)$ the inequality $v_2^N(x, \lambda) \neq 0$, $x \in [x_{N-1}, 1]$ is satisfied (then $x_{N-1} = -1 + (N - 1.5)h = 1 - 1.5h > 1 - (1 - x_{m\text{max}}^m) = x_{m\text{max}}^m$) and therefore $v_1^N(x, \lambda)$ and $v_2^N(x, \lambda)$ are linearly independent.

Since from (4), (5)

$$
v_1^1(x, \lambda) = 1 + \int_{x_0}^{x} \frac{1}{k(t)} \int_{x_0}^{t} (q(\xi) - \lambda r(\xi)) v_1^1(\xi, \lambda) \, d\xi \, dt,
$$

$$
v_1^j(x, \lambda) = \int_{x_{j-1}}^{x} \frac{1}{k(t)} \left[ 1 + \int_{x_{j-1}}^{t} (q(\xi) - \lambda r(\xi)) v_1^1(\xi, \lambda) \, d\xi \right] \, dt, \quad j = 2, \ldots, N,
$$

then according to (3) and to the mean value theorem, there exists a point \( \bar{x} \in (x_{j-1}, x) \) such that
\[
v_1^i(x, \lambda) \geq 1 - \frac{1}{k(t)} \int_{x_0}^{t} q(\xi) - \lambda r(\xi) \left| v_1^i(\xi, \lambda) \right| d\xi dt \geq 1 - \frac{C_4 + \lambda C_6}{C_1(1 - \bar{x}^2)} (x - x_0) \int_{x_0}^{\bar{x}} \left| v_1^i(\xi, \lambda) \right| d\xi,
\]
\[
v_1^i(x, \lambda) \geq \int_{x_{j-1}}^{x} \frac{1}{k(t)} \left( 1 - \int_{x_{j-1}}^{t} q(\xi) - \lambda r(\xi) \left| v_1^i(\xi, \lambda) \right| d\xi \right) dt
\]
\[
\geq \int_{x_{j-1}}^{x} \frac{dt}{k(t)} \left( 1 - (C_4 + \lambda C_6) \int_{x_{j-1}}^{x} \left| v_1^i(\xi, \lambda) \right| d\xi \right)
\]
\[
= \int_{x_{j-1}}^{x} \frac{dt}{k(t)} \left( 1 - (C_4 + \lambda C_6)(x - x_{j-1}) \left| v_1^i(\bar{x}, \lambda) \right| \right).
\]

From these inequalities, it follows that \( v_1^i(x, \lambda) > 0, j = 1, 2, \ldots, N \) on the interval \( (x_{j-1}, x_{j-1} + \delta) \) for any small \( \delta > 0 \). Since the functions \( v_1^i(x, \lambda), j = 1, 2, \ldots, N \) are of constant sign, they are positive on the entire interval \( (x_{j-1}, x_{j+1}) \).

2) Proof is carried out by analogy with the proof of the corresponding properties from [10, p. 141].

The following assertion is valid.

**Lemma 2.** Suppose that the assumptions (3) is satisfied. Then, for
\[
h \leq h_0 = \frac{1}{2} \sqrt{\frac{C_1(1 - x_{j+1}^2)}{C_4 + \lambda C_6}}
\]
the following assertions are valid:

(i) The pattern functions have the properties: \( v_1^i(x, \lambda), j = 2, 3, \ldots, N \) increase monotonically on \( (x_{j-1}, x_{j+1}) \), and the functions \( v_2^i(x, \lambda), j = 1, 2, \ldots, N - 1 \) decrease monotonically on \( [x_{j-1}, x_{j+1}] \);

(ii) For all \( j = 3 - \alpha, 4 - \alpha, \ldots, N + 1 - \alpha, \alpha = 1, 2 \), it holds that
\[
\frac{2}{3C_2(1 + x)(1 - x_{j+1})^\alpha} \leq \frac{v_2^i(x, \lambda)}{|x - x_{j+1}|^\alpha} \leq \frac{2}{C_1(1 - x)(1 + x_{j+1})^\alpha}.
\]

**Proof.** We only prove the assertions for the pattern function \( v_1^i(x, \lambda) \) since those for the \( v_2^i(x, \lambda) \) follow analogously.

Note that equation (8) in connection with assumptions (3) leads, for any bounded \( \lambda \), to the inequality
\[
v_1^i(x, \lambda) \leq \int_{x_{j-1}}^{x} \frac{dt}{1 - t^2} \left[ \frac{1}{C_1} + \frac{C_4 + \lambda C_6}{C_1} \int_{x_{j-1}}^{x} v_1^i(t, \lambda) dt \right]
\]
\[
= \frac{1}{2} \ln \left( 1 + \frac{2(x - x_{j-1})}{(1 - x)(1 + x_{j-1})} \right) \left[ \frac{1}{C_1} + \frac{C_4 + \lambda C_6}{C_1} \int_{x_{j-1}}^{x} v_1^i(t, \lambda) dt \right].
\]

Using the well-known inequality
\[
\frac{r}{r + 1} \leq \ln(1 + r) \leq r,
\]
which is true for \( r \geq 0 \), we thus obtain
\[
v_1^i(x, \lambda) \leq \frac{x - x_{j-1}}{(1 - x)(1 + x_{j-1})} \left[ \frac{1}{C_1} + \frac{C_4 + \lambda C_6}{C_1} \int_{x_{j-1}}^{x} v_1^i(t, \lambda) dt \right].
\]

We now make the substitution
\[
\bar{v}_1^i(x, \lambda) = \frac{v_1^i(t, \lambda)(1 - x)(1 + x_{j-1})}{x - x_{j-1}}
\]
in order to obtain
\[
\bar{v}_1^i(x, \lambda) \leq \frac{1}{C_1} + \frac{C_4 + \lambda C_6}{C_1(1 + x_{j-1})} \int_{x_{j-1}}^{x} \frac{t - x_{j-1}}{1 - t} \bar{v}_1^i(t, \lambda) dt.
\]
Applying the Gronwall inequality (see, e.g., [11, p. 37]), we obtain
\[ v^j_1(x, \lambda) \leq \frac{1}{C_1} \exp \left\{ \frac{C_4 + \lambda C_6}{C_1(1 + x_{j-1})} \int_{x_{j-1}}^{x} \frac{t - x_{j-1}}{1 - t} \, dt \right\} \]
or, equivalently,
\[ v^j_1(t, \lambda) \leq \frac{1}{C_1(1 - x)(1 + x_{j-1})} \exp \left\{ \frac{C_4 + \lambda C_6}{C_1(1 + x_{j-1})} \int_{x_{j-1}}^{x} \frac{t - x_{j-1}}{1 - t} \, dt \right\} \quad \forall x \in [x_{j-1}, x_{j+1}]. \]

From the last estimate and the equality
\[ v^j_1 \text{ grows monotonically,} \]
follows the inequality
\[ k(x) \frac{dv^j_1(x, \lambda)}{dx} = 1 + \int_{x_{j-1}}^{x} (g(\xi) - \lambda r(\xi)) v^j_1(\xi, \lambda) \, d\xi, \]
which holds which proves that \( v^j_1(x, \lambda) \) grows monotonically on \((x_{j-1}, x_{j+1}]\) given that the function \( g(t) = 2 - e^t \) decreases monotonically, \( g(1/2) > 0 \) and the validity of condition (9).

Returning to equality (8), we obtain with the help of the proved assertion (i) that
\[ v^j_1(x, \lambda) \leq \frac{1}{C_1} \int_{x_{j-1}}^{x} \frac{dt}{1 - t^2} + \frac{C_4 + \lambda C_6}{2C_1} v^j_1(x, \lambda) \int_{x_{j-1}}^{x} \frac{t - x_{j-1}}{1 - t^2} \, dt \]
\[ = \frac{1}{2C_1} \ln \left( 1 + \frac{2(x - x_{j-1})}{(1 - x)(1 + x_{j-1})} \right) + \frac{C_4 + \lambda C_6}{4C_1} v^j_1(x, \lambda) \times (x - x_{j-1}) \left[ \ln \left( 1 + \frac{x - x_{j-1}}{1 - x} \right) - \ln \left( 1 + \frac{1 - (1 - x)(1 + x_{j-1})}{1 - x} \right) \right]. \]

Using the inequality (11), we get
\[ v^j_1(x, \lambda) \leq \frac{x - x_{j-1}}{C_1(1 - x)(1 + x_{j-1})} + \frac{C_4 + \lambda C_6}{2C_1} v^j_1(x, \lambda) \frac{(x - x_{j-1})^2}{1 - x^2}, \]
and
\[ v^j_1(x, \lambda) \geq \frac{1}{2C_2} \ln \left( 1 + \frac{2(x - x_{j-1})}{(1 - x)(1 + x_{j-1})} \right) - \frac{C_4 + \lambda C_6}{2C_1} v^j_1(x, \lambda) \frac{(x - x_{j-1})^2}{1 - x^2} \]
\[ \geq \frac{x - x_{j-1}}{C_2(1 + x)(1 - x_{j-1})} - \frac{C_4 + \lambda C_6}{2C_1} v^j_1(x, \lambda) \frac{(x - x_{j-1})^2}{1 - x^2}. \]

Hence,
Algorithmic implementation of an exact three-point difference scheme for a certain class . . .

\[
\frac{v_1^j(x, \lambda)}{x - x_{j-1}} \left(1 - \frac{2(C_4 + \lambda C_6)h^2}{C_1(1 - x_{j+1}^2)}\right) \leq \frac{1}{C_1(x - 1)(1 - x_{j-1})},
\]

\[
\frac{v_1^j(x, \lambda)}{x - x_{j-1}} \left(1 + \frac{2(C_4 + \lambda C_6)h^2}{C_1(1 - x_{j+1}^2)}\right) \geq \frac{1}{C_2(1 + x)(1 - x_{j-1})},
\]

which, taking the condition (9) into account, proves the estimate (10).

Lemma 3. Suppose that the assumptions of Lemma 2 are satisfied. Then, for the problem (1)–(3) there exists ETDS of the form

\[
\begin{align*}
\Lambda y_j + \lambda y_j & y_j \equiv (a y_j)_{x,j} - d_j y_j + \lambda y_j = 0, & j = 1, 2, \ldots, N, & y_0 \neq \infty, & y_{N+1} \neq \infty,
\end{align*}
\]

where

\[
\begin{align*}
y_{x,j} &= \frac{y_j - y_{j-1}}{h}, & y_{x,j} &= \frac{y_{j+1} - y_j}{h}, & a_j &= \left[\frac{1}{h} v_1^j(x_j, \lambda)\right]^{-1}, & j = 2, 3, \ldots, N, \\
a_1 &= a_{N+1} = 0, & d_j &= T_{x,j}(q, \lambda), & \rho_j &= T_{x,j}(r, \lambda), & j = 1, 2, \ldots, N,
\end{align*}
\]

\[
T_{x,j}(\omega(\xi), \lambda) = \frac{1}{h v_1^j(x_j, \lambda)} \int_{x_{j-1}}^{x_j} v_1^j(\xi, \lambda) w(\xi) d\xi + \frac{1}{h v_1^j(x_j, \lambda)} \int_{x_j}^{x_{j+1}} v_1^j(\xi, \lambda) w(\xi) d\xi,
\]

and

\[
\begin{align*}
0 &< (1 - x_{j-1/2}^2)C_1^j \leq a_j \leq (1 - x_{j-1/2}^2)C_2^j, & C_1^j &= \frac{C_1}{2}, & C_2^j &= \frac{3C_2}{2}, & x_{j-1/2} = x_j - \frac{h}{2}, \\
0 &< C_3^j \leq d_j \leq C_4^j, & C_4^j &= 2C_4, & 0 < C_5^j \leq \rho_j \leq C_6^j, & C_6^j &= 2C_6.
\end{align*}
\]

The solution \(y(x)\) of problem (12) coincides with the solution \(u(x)\) of the original problem (1), (2) at nodes of the grid \(\omega_0\), up to a constant multiplier.

Proof. First of all, we note that the problem (1), (2) is equivalent to the sequence of problems

\[
\begin{align*}
\frac{d}{dx} \left[k(x) \frac{du}{dx}\right] - q(x) u(x) &= -\lambda r(x) u(x), & x \in (x_0, x_2), \\
\frac{d}{dx} \left[k(x) \frac{du}{dx}\right]|_{x=x_0} &= 0, & u(x_2) &= u_2,
\end{align*}
\]

\[
\begin{align*}
\frac{d}{dx} \left[k(x) \frac{du}{dx}\right] - q(x) u(x) &= -\lambda r(x) u(x), & x \in (x_{j-1}, x_{j+1}), \\
u(x_{j-1}) &= u_{j-1}, & u(x_{j+1}) &= u_{j+1}, & j = 2, 3, \ldots, N - 1,
\end{align*}
\]

\[
\begin{align*}
\frac{d}{dx} \left[k(x) \frac{du}{dx}\right] - q(x) u(x) &= -\lambda r(x) u(x), & x \in (x_{N-1}, x_{N+1}), \\
u(x_{N-1}) &= u_{N-1}, & k(x) \frac{du}{dx}|_{x=x_{N+1}} &= 0,
\end{align*}
\]

whose Green's functions have the form

\[
G^j(x, \xi) = \frac{1}{v_1^j(x_{j+1}, \lambda)} \begin{cases} v_1^j(x, \lambda) v_2^j(\xi, \lambda), & x_{j-1} \leq x \leq \xi, \\
v_1^j(\xi, \lambda) v_2^j(x, \lambda), & \xi \leq x \leq x_{j+1}, & j = 1, 2, \ldots, N.
\end{cases}
\]

We construct an exact three-point difference scheme. For this purpose, we write the obvious integral representation of (16)–(18). Then, we have

\[
\int_{x_{j-1}}^{x_{j+1}} G^j(x, \xi) \frac{d}{d\xi} \left[k(\xi) \frac{du}{d\xi}\right] d\xi - \int_{x_{j-1}}^{x_{j+1}} G^j(x, \xi) [q(\xi) - \lambda r(\xi)] u(\xi) d\xi = 0, & j = 1, 2, \ldots, N.
\]

Calculating the integral in the left-hand side of (19) by integration by parts and using (4)–(6), we get

\[
\begin{align*}
- v_1^j(x, \lambda) k(\xi) v_2^j(\xi, \lambda) u(\xi)|_{x_{j+1}} - v_1^j(x, \lambda) k(\xi) v_2^j(\xi, \lambda) u(\xi)|_{x_{j-1}} = 0.
\end{align*}
\]

For \( j = 1 \), we have
\[
\frac{v_1(x, \lambda)}{v_1(x_2, \lambda)} \left[ u_2 + k(x) \frac{dv_1(x, \lambda)}{dx} u(x) \right] - \frac{v_1(x, \lambda)}{v_1(x_2, \lambda)} k(x) \frac{dv_1(x, \lambda)}{dx} u(x) = 0.
\]

From (4) and (5), it follows that
\[
k(x) \frac{dv_1(x, \lambda)}{dx} = \int_{x_0}^{x} [q(\xi) - \lambda r(\xi)] v_1(\xi, \lambda) d\xi,
\]
and
\[
k(x) \frac{dv_1(x, \lambda)}{dx} = -1 - \int_{x}^{x_2} [q(\xi) - \lambda r(\xi)] v_2(\xi, \lambda) d\xi. \tag{21}
\]

Thus,
\[
\frac{v_1(x, \lambda)}{v_1(x_2, \lambda)} \left[ u_2 - u(x) \left( 1 + \int_{x}^{x_2} [q(\xi) - \lambda r(\xi)] v_1(\xi, \lambda) d\xi \right) \right]
- \frac{v_1(x, \lambda)}{v_1(x_2, \lambda)} u(x) \int_{x_0}^{x} [q(\xi) - \lambda r(\xi)] v_1(\xi, \lambda) d\xi = 0. \tag{22}
\]

For \( x = x_1 \), let us multiply equality (22) by \( \frac{v_1(x, \lambda)}{\lambda v_1(x_2, \lambda) v_2(x, \lambda)} \). Note that due to \( v_2(x, \lambda) = v_0(x, \lambda) \), we have
\[
\frac{u_2 - u_1}{\lambda v_1(x, \lambda)} - u_1 \left[ \frac{1}{\lambda v_1(x_1, \lambda)} \int_{x_1}^{x_2} [q(\xi) - \lambda r(\xi)] v_1(\xi, \lambda) d\xi \right]
+ \frac{1}{\lambda v_1(x_1, \lambda)} \int_{x_0}^{x_1} [q(\xi) - \lambda r(\xi)] v_1(\xi, \lambda) d\xi = 0,
\]
or, equivalently, in view of \( a_1 = 0 \),
\[
\frac{1}{\lambda} (a_2 u_{x_1} - a_1 u_{x_1}) - d_1 u_1 + \lambda r_1 u_1 = 0.
\]

For \( j = 2, 3, \ldots, N - 1 \), equality (20) has the form
\[
\frac{v_1(x, \lambda)}{v_1(x_j, \lambda)} \left[ u_{j+1} + k(x) \frac{dv_1(x, \lambda)}{dx} u(x) \right] + \frac{v_2(x, \lambda)}{v_1(x_j, \lambda)} \left[ u_{j-1} - k(x) \frac{dv_1(x, \lambda)}{dx} u(x) \right] = 0. \tag{23}
\]

Since it follows from (5) that
\[
k(x) \frac{dv_1(x, \lambda)}{dx} = (-1)^{\alpha+1} + \int_{x_{j+1}}^{x} [q(\xi) - \lambda r(\xi)] v_1(\xi, \lambda) d\xi, \quad \alpha = 1, 2, \tag{24}
\]
we have
\[
\frac{v_1(x, \lambda)}{v_1(x_j, \lambda)} \left[ u_{j+1} - \left( 1 + \int_{x_{j+1}}^{x} [q(\xi) - \lambda r(\xi)] v_2(\xi, \lambda) d\xi \right) u(x) \right]
+ \frac{v_2(x, \lambda)}{v_1(x_j, \lambda)} \left[ u_{j-1} - \left( 1 + \int_{x_{j-1}}^{x} [q(\xi) - \lambda r(\xi)] v_1(\xi, \lambda) d\xi \right) u(x) \right] = 0. \tag{25}
\]

Taking in (24) \( x = x_j \), multiplying the obtained equality by \( \frac{v_1(x_{j+1}, \lambda)}{\lambda v_1(x, \lambda) v_2(x, \lambda)} \), and using the properties of the pattern functions \( v_1(x_{j+1}, \lambda) = v_2(x_{j-1}, \lambda) \), \( v_2(x, \lambda) = v_1(x_j, \lambda) \), we arrive at the exact three-point difference scheme (12) for \( j = 2, 3, \ldots, N - 1 \).

Let us rewrite (20) for \( j = N \) by
\[
\frac{v_1^N(x, \lambda)}{v_1^N(x_{N+1}, \lambda)} k(x) \frac{dv_1^N(x, \lambda)}{dx} u(x) + \frac{v_2^N(x, \lambda)}{v_1^N(x_{N+1}, \lambda)} \left[ u_{N-1} - k(x) \frac{dv_1^N(x, \lambda)}{dx} u(x) \right] = 0.
\]

Then, considering the equalities
\[
k(x) \frac{dv_1^N(x, \lambda)}{dx} = 1 + \int_{x_{N+1}}^{x} [q(\xi) - \lambda r(\xi)] v_1^N(\xi, \lambda) d\xi,
\]
and
\[
k(x) \frac{dv_2^N(x, \lambda)}{dx} = - \int_{x}^{x_{N+1}} [q(\xi) - \lambda r(\xi)] v_2^N(\xi, \lambda) d\xi, \tag{25}
\]

which follow from (5) and (6), we obtain
\[
- \frac{u_1^N(x, \lambda)}{v_1^N(x_{N+1}, \lambda)} \int_x^{x_{N+1}} [q(\xi) - \lambda r(\xi)] v_2^N(\xi, \lambda) \, d\xi \cdot u(x) \\
+ \frac{v_1^N(x, \lambda)}{v_1^N(x_{N+1}, \lambda)} \left[ u_{N+1} - \left( 1 + \int_{x_{N-1}}^{x} [q(\xi) - \lambda r(\xi)] v_1^N(\xi, \lambda) \, d\xi \right) u(x) \right] = 0. \tag{26}
\]

Taking \( x = x_N \) and multiplying the obtained equality by \( \frac{v_1^N(x_{N+1}, \lambda)}{hv_1^N(x_N, \lambda)v_2^N(x_N, \lambda)} \), we obtain
\[
- \frac{u_N - u_{N+1}}{h v_1^N(x_N, \lambda)} - u_N \left[ \frac{1}{h v_1^N(x_N, \lambda)} \int_{x_N}^{x_{N+1}} [q(\xi) - \lambda r(\xi)] v_2^N(\xi, \lambda) \, d\xi \\
+ \frac{1}{h v_1^N(x_N, \lambda)} \int_{x_{N-1}}^{x_N} [q(\xi) - \lambda r(\xi)] v_1^N(\xi, \lambda) \, d\xi \right] = 0,
\]
which due to \( a_{N+1} = 0 \), can be written as
\[
\frac{1}{h} (a_{N+1} u_{x,N} - a_N u_{x,N}) - d_N u_N + \lambda \rho_N u_N = 0.
\]

Inequality (14) follows from (10). Indeed,
\[
a_j = \frac{h}{v_1(x_j, \lambda)} \leq \frac{3}{2} C_2 (1 + x_j)(1 - x_j) \leq \frac{3}{2} C_2 (1 - x_j^2),
\]
\[
a_j \geq \frac{1}{2} C_2 (1 - x_j)(1 + x_j) - \frac{1}{2} C_2 (1 - x_j^2), \quad j = 2, 3, \ldots, N.
\]

We now prove estimate (15). Since
\[
d_j = \frac{1}{h v_1^2(x_j, \lambda)} \int_{x_{j-1}}^{x_j} v_1^2(\xi, \lambda) q(\xi) \, d\xi + \frac{1}{h v_2^2(x_j, \lambda)} \int_{x_j}^{x_{j+1}} v_2^2(\xi, \lambda) q(\xi) \, d\xi,
\]
in view of the positivity and monotonicity of functions \( v_1(x, \lambda), v_2(x, \lambda) \) we have
\[
d_j \leq \frac{C_4}{h} \left[ \int_{x_{j-1}}^{x_j} v_1^2(\xi, \lambda) \, d\xi + \int_{x_j}^{x_{j+1}} v_2^2(\xi, \lambda) \, d\xi \right] \leq 2C_4.
\]

In addition, using estimates (10), we obtain
\[
d_j \geq \frac{C_3}{h} \left[ \int_{x_{j-1}}^{x_j} v_1^2(\xi, \lambda) \, d\xi + \int_{x_j}^{x_{j+1}} v_2^2(\xi, \lambda) \, d\xi \right] \geq C_3'.
\]

Analogously, the inequality \( 0 < C_3' \leq \rho_j \leq 2C_6 \) can be proven.

Note that if the solution of problem (1) is normalized by the condition
\[
\int_0^1 r(x) u^2(x) \, dx = 1,
\]
then, for the exact normalization on the grid, we have
\[
\sum_{j=2}^N \int_{x_{j-1}}^{x_j} r(x) \left[ \frac{v_1^j(x, \lambda)}{v_1^j(x_j, \lambda)} y_j + \frac{v_2^{j-1}(x, \lambda)}{v_2^{j-1}(x_{j-1}, \lambda)} y_{j-1} \right]^2 \, dx
\]
\[
+ \int_{x_{N-1}}^{x_N} r(x) \left[ \frac{v_1^1(x, \lambda)}{v_1^1(x_N, \lambda)} y_1 \right]^2 \, dx + \int_{x_{N-1}}^{x_N} r(x) \left[ \frac{v_2^N(x, \lambda)}{v_2^N(x_N, \lambda)} y_N \right]^2 \, dx = 1.
\]

3. Coefficient stability of ETDS

When calculating the coefficients of difference schemes, errors are inevitable. Therefore, it is natural to require coefficient stability of difference schemes, i.e., stability to perturbations of the coefficients (see [1]). In the following, we prove the coefficient stability of the constructed difference schemes. The property of coefficient stability of a difference scheme allows us to prove the convergence of truncated three-point difference schemes.
We consider the difference problem (12) in the space $H_h$ of grid functions $y$ with the following scalar product and norms:

$$(y, v) = \sum_{\xi \in \omega_h} h y(\xi) v(\xi), \quad \|y\| = (y, y)^{1/2}, \quad \|y\|_C = \max_{\xi \in \omega_h} |y(\xi)|.$$ 

Suppose that $\lambda^h = \lambda^h_n$ is the $n$th eigenvalue of this problem, and that $y = y_n$ is the normalized eigenfunction. There exist $N$ real eigenvalues $\lambda_1^h, \lambda_2^h, \ldots, \lambda_N^h$, to which the appropriate eigenfunctions $y_1, y_2, \ldots, y_N$ correspond. The eigenfunctions are orthonormalized with weight $\rho$, such that $(\rho y_n, y_m) = 0$ holds for $n \neq m$ and $(\rho y_n, y_n) = 1$.

Multiplying (12) scalarwise by $y$ and taking the difference Green formula (see [10, p. 47]) and the equalities $a_1 = a_{N+1} = 0$ into account, we find

$$\lambda^h = R_N(y) = \frac{(a, y^2) + (d, y^2)}{(\rho, y^2)}.$$ 

It is easy to see that the difference problem (12) is equivalent to the variational problem

$$\lambda^h = \min_y R_N(y), \quad \lambda^h = \max_{y_m} \min_{(\rho y_n, y_m) = 0} R_N(y), \quad m = 1, 2, \ldots, n - 1, \quad n = 2, 3, \ldots, N.$$ 

The following assertion is valid (see [4]):

**Lemma 4.** For the eigenvalues and the eigenfunctions of problem (12)–(15) the following estimates are satisfied:

$$M_1 n^2 \leq \lambda^h \leq M_2 n^2, \quad \left\| \sqrt{\rho} y_n \right\|_C \leq M_3 \sqrt{n}, \quad \|a(y_n)\|_C \leq M_4 n^{3/2},$$

where the constants $M_1$, $M_2$, $M_3$, $M_4$ do not depend on $h$ and $n$, $n = 1, 2, \ldots, N$.

Together with the ETDS (12)–(15), we consider the perturbed three-point difference scheme

$$\tilde{\Lambda} \tilde{y} + \lambda^h \tilde{\rho} \tilde{y} = 0, \quad x \in \omega_h, \quad \bar{y}_0 \neq \infty, \quad \bar{y}_{N+1} \neq \infty,$$

where

$$\tilde{\Lambda} \tilde{y} = (\bar{a} \tilde{y}_x) - \tilde{d} \tilde{y}, \quad x \in \omega_h, \quad \bar{a} = \bar{a}_{N+1} = 0.$$ 

Introducing a function $\tilde{z} = y - \bar{y}$, we obtain the boundary value problem

$$\Lambda \tilde{z} + \lambda^h \tilde{\rho} \tilde{z} = -\Psi(x), \quad x \in \omega_h, \quad z_0 \neq \infty, \quad z_{N+1} \neq \infty,$$

where

$$\Psi(x) = \Lambda \bar{y} + \lambda^h \tilde{\rho} \bar{y}. $$

Using the equation (29), we can rewrite the function $\Psi(x)$ into

$$\Psi(x) = \Lambda \bar{y} + \lambda^h \tilde{\rho} \bar{y} - \tilde{\Lambda} \tilde{y} - \lambda^h \tilde{\rho} \bar{y} = ((a - \bar{a}) \tilde{y}_x) - (d - \bar{d}) \tilde{y} + \tilde{\lambda}^h (\rho - \bar{\rho}) \bar{y} + (\lambda^h - \tilde{\lambda}^h) \tilde{\rho} \bar{y} = \psi(x) + (\lambda^h - \tilde{\lambda}^h) \tilde{\rho} \bar{y},$$

where

$$\psi(x) = \eta_x + \psi^*(x), \quad \eta = (a - \bar{a}) \tilde{y}_x, \quad \psi^* = -(d - \bar{d}) \tilde{y} + \tilde{\lambda}^h (\rho - \bar{\rho}) \bar{y}. $$

The parameter $\lambda^h$ is an eigenvalue for the difference operator of problem (30). Thus, the inhomogeneous equation (30) is solvable only if the eigenfunction $y(x)$ is orthogonal to the right-hand side of equation (30), or, more precisely, if the equality

$$(\Psi, y) = (\psi, y) + (\lambda^h - \tilde{\lambda}^h) (\tilde{\rho} \bar{y}, y) = 0$$

is satisfied.

Only a single eigenfunction, determined accurately up to an arbitrary multiplier $C_0$, corresponds to the eigenvalue $\lambda^h$. We choose this multiplier in a way such that the function $\bar{y} = C_0 \tilde{y}$ is orthogonal to the difference $\bar{z} = \bar{y} - \tilde{y}$:

$$(\tilde{\rho} \bar{y}, \bar{z}) = 0.$$
Due to the normalization condition \((ρy, y) = 1\), we thus obtain

\[(ρy, y) = (ρ\bar{y}, \bar{y} - \bar{z}) = (ρy, \bar{y}) - (ρ, \bar{z}) = C_0(ρy, y) = C_0.\]

If \(\bar{y} \to y\) as \(h \to 0\), we can assume that \(C_0 > 0\).

Further,

\[
(ρ, \bar{y}^2) = (ρ, (\bar{y} - \bar{z})^2) = (ρ, \bar{y}^2) - 2(ρ, \bar{z}\bar{y}) + (ρ, \bar{z}^2) = C_0^2(ρy, y) + (ρ, \bar{z}^2) = C_0^2 - (ρ, \bar{z}\bar{y}),
\]

is valid and, hence,

\[
1 - C_0^2 = -(ρ, \bar{z}\bar{y}) - [(ρ, \bar{y}^2) - (ρ, \bar{y}^2)].
\]

We use equality (32) for determining \(λ^h - \bar{λ}^h\):

\[
λ^h - \bar{λ}^h = \frac{⟨\psi, y⟩}{(ρy, y)} = -\frac{⟨\psi, y⟩}{C_0^2}.
\]

We transform the right-hand side of equation (35) by taking (31), the summation by parts formula (see, e.g., [10, p. 47]), and the equalities \(a_1 = a_{N+1} = 0\) into account

\[
⟨\psi, \bar{y}⟩ = -⟨η, \bar{y}_x⟩ + (ψ^*, \bar{y}).
\]

From this and the estimates (28) for \(\bar{y}, \bar{y}_x\), we find

\[
|λ^h - \bar{λ}^h| \leq \frac{|⟨\psi, \bar{y}⟩|}{C_0^2} \leq \frac{|⟨η, \bar{y}_x⟩| + |⟨ψ^*, \bar{y}⟩|}{C_0^2}
\]

\[
\leq \frac{|\bar{y}_x|C(1, |η|) + |\bar{y}|C(1, |ψ^*|)}{C_0^2} \leq Mn^{3/2}[(1, |η|) + (1, |ψ^*|)].
\]

We arrive at the following assertion.

**Lemma 5.** Suppose that the conditions (14), (15) for the difference Sturm–Liouville problem (12) are satisfied. Then, the estimate

\[
|λ^h_n - \bar{λ}^h_n| \leq Mn^{3/2}[(1, |η|) + (1, |ψ^*|)]
\]

is valid, where the constant \(M > 0\) depends on \(C_i, i = 1, 2, \ldots, 6, \) and \(C_0\).

We now find an estimate for \(\bar{z}\). Since \(\bar{y} = C_0y\), we see that \(y\) satisfies equation (12) and \((ρ, \bar{y}^2) = C_0^2\), and for \(\bar{z} = \bar{y} - \bar{y}\) we arrive at problem (30).

This problem is reduced to a discrete analogue of the integral equation

\[
\bar{z}(x) = λ^h(G(x, ξ), ρ(ξ)\bar{z}(ξ)) + (G(x, ξ), Ψ(ξ)),
\]

where \(G(x, ξ) = G^h(x, ξ)\) is the difference Green function of the operator \(Λy = (ay_x)_x - dy\) with boundary conditions \(y_0 \neq \infty, y_{N+1} \neq \infty\) (see [4]).

The eigenfunction \(\bar{y}\) of problem (12) satisfies the equation

\[
\bar{y}(x) = λ^h(G(x, ξ), ρ(ξ)\bar{y}(ξ))
\]

We transform equations (37) and (38) into such a form such that the corresponding kernels become symmetric. For this purpose, we use the substitutions

\[
v(x) = √ρ(x)\bar{z}(x), \quad ϕ(x) = √ρ(x)\bar{y}(x), \quad K(x, ξ) = √ρ(x)ρ(ξ)G(x, ξ).
\]

Then equations (37) and (38) take the form

\[
v_n(x) = λ^h_n(K(x, ξ), v_n(ξ)) + f(x), \quad f(x) = (K(x, ξ), Ψ(ξ)), \quad Ψ(ξ) = \frac{Ψ(ξ)}{√ρ(ξ)}, \quad \bar{Ψ}(ξ) = \frac{Ψ(ξ)}{√ρ(ξ)}.
\]

The condition of orthogonality of the function \(f(x)\) to functions \(ϕ_n(x)\) is satisfied in view of condition (32):

\[
(ϕ_n(x), f(x)) = (ϕ_n(x), (K(x, ξ), Ψ(ξ))) = (Ψ(ξ), (K(x, ξ), ϕ_n(x)))
\]

\[
= \frac{1}{λ^h_n}(Ψ(ξ), ϕ_n(ξ)) = \frac{1}{λ^h_n}(Ψ(ξ), ϕ_n(ξ)) = \frac{1}{λ^h_n}(Ψ(ξ), ϕ_n(ξ)) = \frac{1}{λ^h_n}(Ψ(ξ), ϕ_n(ξ)) = 0.
\]

We rewrite condition (33) as

\[
(ϕ_n, v_n) = 0.
\]
Searching for the solution \( v(x) = v_n(x) \) of equation (39) of the form
\[
v_n(x) = f(x) + \sum_{k=1}^{N-1} c_k \varphi_k(x)
\] (42)
under the additional condition (41), we substitute this expression to the right-hand side of equation (39) to obtain
\[
v_n(x) = f(x) + \lambda_n^h \sum_{k=1, k \neq n}^{N-1} c_k (K(x, \xi), \varphi_k(\xi)) + \lambda_n^h (K(x, \xi), f(\xi)).
\] (43)

Expanding \( f(x) \) by the eigenfunctions \( \{ \varphi_k(x) \} \)
\[
f(x) = \sum_{k=1, k \neq n}^{N-1} f_k \varphi_k(x), \quad f_k = (f, \varphi_k),
\]
it follows that
\[
(K(x, \xi), f(\xi)) = \sum_{k=1, k \neq n}^{N-1} \frac{f_k}{\lambda_k^h} \varphi_k(x).
\]

Thus, in view of (40), we can rewrite equality (43) into
\[
v_n(x) = f(x) + \lambda_n^h \sum_{k=1, k \neq n}^{N-1} \left[ \frac{c_k}{\lambda_k^h} + \frac{f_k}{\lambda_k^h} \right] \varphi_k(x).
\] (44)

Due to equality (44), we have
\[
c_k = (v_n - f, \varphi_k) = \frac{\lambda_n^h}{\lambda_k^h} c_k + \frac{\lambda_n^h}{\lambda_k^h} (f, \varphi_k),
\]
and substituting \( c_k = \lambda_n^h (f, \varphi_k) / (\lambda_k^h - \lambda_n^h) \) into (42), we obtain
\[
v_n(x) = f(x) + \sum_{k=1, k \neq n}^{N-1} \frac{\lambda_n^h (f, \varphi_k)}{\lambda_k^h - \lambda_n^h} \varphi_k(x).
\] (45)

Multiplying the equation (45) by \( a^\mu(x) \), \( 0 < \mu \leq 1 \), we can estimate the second term on the right-hand side of this equation by
\[
\left| \sum_{k=1, k \neq n}^{N-1} \frac{\lambda_n^h (f, \varphi_k)}{\lambda_k^h - \lambda_n^h} a^\mu(x) \varphi_k(x) \right| \leq \| f \| \| a^\mu \varphi_k \| \lambda_n^h \sum_{k=1, k \neq n}^{N-1} \left| \frac{c_k}{\lambda_k^h} + \frac{f_k}{\lambda_k^h} \right| \| f \| \lambda_n^h \sum_{k=1, k \neq n}^{N-1} \frac{1}{|\lambda_k^h - \lambda_n^h|}.\]

Let \( \varepsilon > 0 \) be an arbitrary number independent of \( h \). We choose the number \( n_0 \) in a way such that \( \lambda_{n_0}^h \geq (1 + \varepsilon) \lambda_n^h \). Then,
\[
\sum_{k=n_0}^{N-1} \frac{(\lambda_n^h)^{1/4}}{|\lambda_k^h - \lambda_n^h|} \leq \frac{1 + \varepsilon}{\varepsilon} \sum_{k=n_0}^{N-1} \frac{(\lambda_n^h)^{1/4}}{\lambda_k^h} \leq \frac{M'}{\varepsilon} \sum_{k=n_0}^{N-1} \frac{1}{(\lambda_k^h)^{3/4}} \leq M,
\]
where the constant \( M > 0 \) is independent of \( h \).

Since \( \lambda_k^h \to \lambda_k \) for \( k \leq n_0 \) as \( h \to 0 \) (see [4], Theorem 1), we have for a sufficiently small \( h \leq h_0 \), that
\[
\sum_{k=1}^{n_0-1} \frac{(\lambda_k^h)^{1/4}}{|\lambda_k^h - \lambda_n^h|} \leq M,
\]
where \( M \) does not depend on \( h \).

Hence, the estimate
\[
\| a^\mu v_n \|_C \leq M \| a^\mu f \|_C
\] (46)
is satisfied.
We transform the expression for $f(x)$ into
\[
f(x) = (K(x, \xi), \Psi(\xi)) = \left( \sqrt{\rho(x)} \sqrt{\rho(\xi)} G(x, \xi), \frac{\Psi(\xi)}{\sqrt{\rho(\xi)}} \right) = \sqrt{\rho(x)} (G(x, \xi), \Psi(\xi))
\]
\[
= (\lambda^h - \bar{\lambda}^h) \sqrt{\rho(x)} (G(x, \xi), \rho(\xi) \tilde{y}(\xi)) + \sqrt{\rho(x)} (G(x, \xi), \eta G(\xi)) + \psi^*(\xi)
\]
\[
= (\lambda^h - \bar{\lambda}^h) \sqrt{\rho(x)} (G(x, \xi), \rho(\xi) \tilde{y}(\xi)) + \sqrt{\rho(x)} \{-(\tilde{a}(\xi)) G(\xi) (x, \xi), \eta G(\xi), (G(x, \xi), \psi^*(\xi))}. 
\]

Hence, taking the estimates (see [4])
\[
\|a^\mu G(x, \xi)\|_C \leq C_7, \quad \|\tilde{a}(\xi) G(\xi) (x, \xi)\|_C \leq C_8,
\]
into account where the constants $C_7, C_8$ do not depend on $h$ and $n$, we obtain
\[
\|a^\mu f\|_C \leq \left( \left( \|a^\mu (x) \tilde{a}(\xi) G(\xi) (x, \xi), \frac{\eta(\xi)}{a(\xi)} \|_C \right) + \|\sqrt{\rho(x)} (a^\mu (x) G(x, \xi), \psi^*(\xi)) \|_C \right)
\]
\[
+ \|\sqrt{\rho(x)} (a^\mu (x) G(x, \xi), \rho(\xi) \tilde{y}(\xi)) \|_C \|\lambda^h - \bar{\lambda}^h\| \leq M_1 \left\{ \left( 1, \frac{\eta}{a} \right) + (1, |\psi^*|) \right\} + M_2 |\lambda^h - \bar{\lambda}^h|.
\]

Substituting this estimate into (46), returning back to the function $\tilde{z}(x) = v(x)/\sqrt{\rho(x)}$ and taking the inequality (28) as well as Lemma 4 into account, yields
\[
\|a^\mu \tilde{z}\|_C \leq M \left\{ \left( 1, \frac{\eta}{a} \right) + (1, |\psi^*|) \right\}.
\]

We are interested in the difference $z = y - \tilde{y}$ which is expressed by
\[
z = \frac{z}{C_0} + \frac{1 - C_0}{C_0} \tilde{y} = \frac{z}{C_0} + \frac{1 - C_0^2}{C_0(1 + C_0)} \tilde{y}.
\]

Since $\|a^\mu \tilde{y}\|_C$ is bounded, it follows that for a sufficiently small $h$, we have
\[
\|a^\mu z\|_C \leq \frac{\|a^\mu \tilde{z}\|_C}{C_0} + \left| \frac{1 - C_0}{C_0(1 + C_0)} \right| \|a^\mu \tilde{y}\|_C \leq M(C_0) \left( \|a^\mu \tilde{z}\|_C + |1 - C_0^2| \right).
\]

As it is apparent from formula (34),
\[
|1 - C_0^2| \leq \left( \rho, \tilde{y}^2 \right)^{1/2} + \left| \left( \rho, \tilde{y}^2 \right) - (\tilde{\rho}, \tilde{y}^2) \right| \leq M_1 \|a^\mu \tilde{z}\|_C + \left| (\rho, \tilde{y}^2) - (\tilde{\rho}, \tilde{y}^2) \right|.
\]

If $\mu$ is chosen as $\mu = 0.5 + \varepsilon$, where $0 < \varepsilon \leq 0.5$, we get
\[
\|a^{0.5+\varepsilon} \tilde{z}\|_C \leq M \left( \|a^{0.5+\varepsilon} \tilde{z}\|_C + \left| (\rho, \tilde{y}^2) - (\tilde{\rho}, \tilde{y}^2) \right| \right).
\]

Inserting the estimate for $\|a^{0.5+\varepsilon} \tilde{z}\|_C$, we make sure that by $\varepsilon \to 0$ the following proposition is true:

**Theorem 1.** Suppose that the assumptions of Lemma 4 are satisfied. Then, for sufficiently small $h \leq h_0$, we have the following estimates:
\[
\|\sqrt{\psi}(y_n - \tilde{y}_n)\|_C \leq M_1 \left\{ \left( 1, \frac{\eta}{a} \right) + (1, |\psi^*|) \right\} + M_2 \left| (\rho, \tilde{y}^2) - (\tilde{\rho}, \tilde{y}^2) \right|,
\]
\[
|\lambda^h - \bar{\lambda}^h| \leq M_3 \left\{ (1, |\eta|) + (1, |\psi^*|) \right\},
\]

where the constants $M_i, i = 1, 2, 3$ depend only on $C_i, i = 1, 2, \ldots, 6$, and $C_0$.

This theorem proves the continuous dependence of the solution of problem (12) on the coefficients, that is, the coefficient stability.

4. **Algorithmic realization of ETDS**

We pass to the algorithmic realization of ETDS (12). First of all, note that this scheme can be written in the form
\[
(ay_j)_{x,j} - (d_j - \lambda p_j) y_j = 0, \quad j = 1, 2, \ldots, N, \quad y_0 \neq \infty, \quad y_{N+1} \neq \infty, \quad (47)
\]
where
\[
a_1 = a_{N+1} = 0, \quad a_j = \left( \frac{1}{\lambda} \right)^{x,j}(x_j, \lambda)^{-1}, \quad j = 2, 3, \ldots, N, \quad (48)
\]

Due to (48), we already have the necessary representation for

\[ d_j - \lambda \rho_j = \frac{1}{h v_1(x_j, \lambda)} \int_{x_{j-1}}^{x_j} v_1^j(\xi, \lambda)[g(\xi) - \lambda r(\xi)] \, d\xi \]
\[ + \frac{1}{h v_2(x_j, \lambda)} \int_{x_j}^{x_{j+1}} v_2^j(\xi, \lambda)[g(\xi) - \lambda r(\xi)] \, d\xi, \quad j = 1, 2, \ldots, N. \quad (49) \]

We express the coefficients \( a_j, d_j - \lambda \rho_j \) of the difference scheme via the solutions of the Cauchy problems (4)–(6). Due to (48), we already have the necessary representation for \( a_j \).

In view of (21), (23) and (25), we rewrite equalities (49) as

\[
\begin{align*}
d_j - \lambda \rho_j &= \frac{1}{h v_1(x_j, \lambda)} \left[ k(x_j) \frac{dv_1^j(x_j, \lambda)}{dx} - 1 \right] + \frac{1}{h v_2(x_j, \lambda)} \left[ -k(x_j) \frac{dv_2^j(x_j, \lambda)}{dx} - 1 \right] \\
&= h^{-1} \sum_{\alpha=1}^{2} (-1)^{\alpha+1} \left[ v_1^\alpha(x_j, \lambda) \right]^{-1} \left[ m_1^\alpha(x_j, \lambda) + (-1)\alpha \right], \quad j = 2, 3, \ldots, N - 1, \\
d_1 - \lambda \rho_1 &= \frac{1}{h v_1(x_1, \lambda)} k(x_1) \frac{dv_1^1(x_1, \lambda)}{dx} + \frac{1}{h v_2(x_1, \lambda)} \left[ -k(x_1) \frac{dv_2^1(x_1, \lambda)}{dx} - 1 \right] \\
&= h^{-1} \sum_{\alpha=1}^{2} (-1)^{\alpha+1} \left[ v_1^\alpha(x_1, \lambda) \right]^{-1} \left[ m_1^\alpha(x_1, \lambda) + \alpha - 1 \right], \\
d_N - \lambda \rho_N &= \frac{1}{h v_1(x_N, \lambda)} \left[ k(x_N) \frac{dv_N^N(x_N, \lambda)}{dx} - 1 \right] + \frac{1}{h v_2(x_N, \lambda)} \left[ -k(x_N) \frac{dv_2^N(x_N, \lambda)}{dx} \right] \\
&= h^{-1} \sum_{\alpha=1}^{2} (-1)^{\alpha+1} \left[ v_1^\alpha(x_N, \lambda) \right]^{-1} \left[ m_1^\alpha(x_N, \lambda) + \alpha - 2 \right],
\end{align*}
\]

where
\[ m_1^\alpha(x, \lambda) = k(x) \frac{dv_1^\alpha(x, \lambda)}{dx}. \]

Thus, the ETDS (47)–(49) can be written in the form

\[
(ay_x)_{x,j} - (d_j - \lambda \rho_j) y_j = 0, \quad j = 2, 3, \ldots, N - 1,
\]
\[
\frac{1}{h} a_2 y_{x,1} - (d_1 - \lambda \rho_1) y_1 = 0, \quad -\frac{1}{h} a_N y_{x,N} - (d_N - \lambda \rho_N) y_N = 0,
\]

where
\[
a_j = \left[ \frac{1}{h} v_1^j(x_j, \lambda) \right]^{-1}, \quad j = 2, 3, \ldots, N,
\]
\[
d_j - \lambda \rho_j = h^{-1} \sum_{\alpha=1}^{2} (-1)^{\alpha+1} \left[ v_1^\alpha(x_j, \lambda) \right]^{-1} \left[ m_1^\alpha(x_j, \lambda) + (-1)^\alpha \right], \quad j = 2, 3, \ldots, N - 1,
\]
\[
d_1 - \lambda \rho_1 = h^{-1} \sum_{\alpha=1}^{2} (-1)^{\alpha+1} \left[ v_1^\alpha(x_1, \lambda) \right]^{-1} \left[ m_1^\alpha(x_1, \lambda) + \alpha - 1 \right],
\]
\[
d_N - \lambda \rho_N = h^{-1} \sum_{\alpha=1}^{2} (-1)^{\alpha+1} \left[ v_1^\alpha(x_N, \lambda) \right]^{-1} \left[ m_1^\alpha(x_N, \lambda) + \alpha - 2 \right].
\]

Thus, for calculating the coefficients \( a_j, d_j - \lambda \rho_j \) of ETDS for any node \( x_j \) of the grid \( \omega_h \), it is necessary to solve two Cauchy problems (4)–(6) with smooth coefficients: at \( \alpha = 1 \) on the interval \([x_{j-1}, x_j]\) (forward) and at \( \alpha = 2 \) on the interval \([x_j, x_{j+1}]\) (backward). If each of the specified Cauchy problems is solved numerically by any one-step method (Taylor series expansion or Runge–Kutta method), we will obtain a truncated difference scheme. The investigation of accuracy and development of the algorithm of finding the solution of such scheme will be performed in further work.
Algorithmic implementation of an exact three-point difference scheme for a certain class

Алгоритмічна реалізація точної триточкової різницевої схеми для деякого класу сингулярних задач Штурма–Ліувілля

У цій статті розроблено нову алгоритмічну реалізацію точних триточкових різницевих схем на нерівномірній сітці для деякого класу сингулярних задач Штурма–Ліувілля. Показано, що для обчислення коефіцієнтів точної схеми в довільному вузлі сітки $x_j$ потрібно розв’язати дві допоміжні задачі Коші для лінійних звичайних диференціальних рівнянь другого порядку: одну на відрізку $[x_{j-1}, x_j]$ (вперед) і одну на відрізку $[x_j, x_{j+1}]$ (назад). Доведено теорему про коефіцієнтну стійкість точної триточкової різницевої схеми.

Ключові слова: сингулярна задача Штурма–Ліувілля; точна триточкова різницева схема; коефіцієнтна стійкість.
